Insights at the surface level

Can you help us predicting the CMC?

Objective: to develop a fully predictive molecular-experimental framework for the design of surfactants

Challenge: the modeling will be incomplete until the CMC could be predicted

Key question: are we missing something obvious?

Abstract

How to obtain the Pore Size Distribution?

• Experimental Isotherm

$$N_T(P) = \int_{H_{min}}^{H_{max}} f(H) \rho_T(P, H) dH$$

• Kernel of Single Isotherms (DFT, **GCMC**)

• PSD

- Ill-posed problem!
- Possible solution:
- A regularization procedure

Suppositions

- Unique Pore Geometry
- Homogeneous Surfaces

The Discrete Picard Condition (DPC)

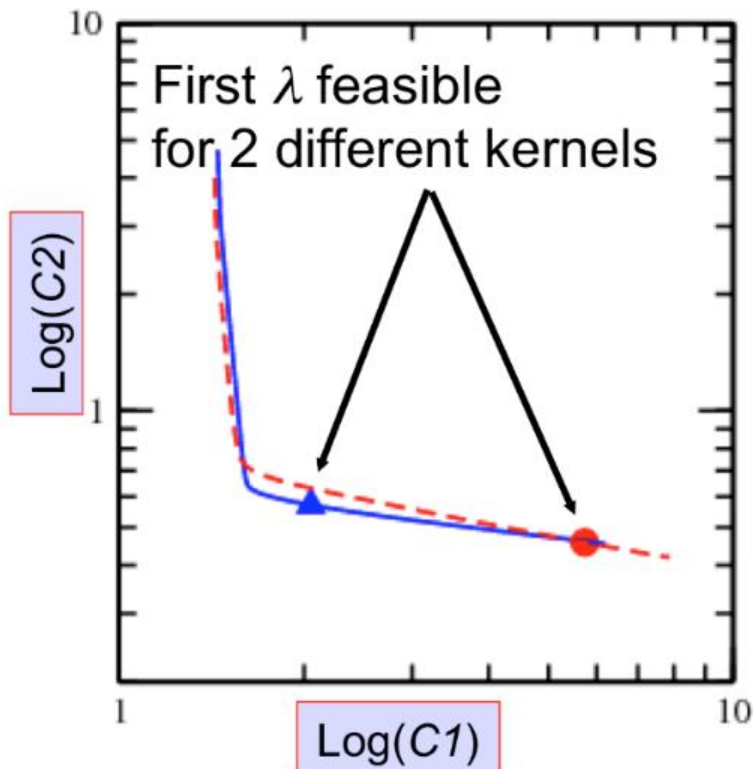

$$r_i \equiv s_i^{-1} \left(\prod_{j=i-q}^{j=i+q} \|u_j^T a_e\| \right)^{1/(2q+1)}$$

The discrete Picard condition (DPC)

r_i : tells how "good" the couple kernel – experimental data is. The red line should have in "average" a negative slope

The L-curve criterion

The L-curve

Depicts many calculated possible solutions in a given range of λ values.

The results of C1, C2 are plotted using log-log axis.

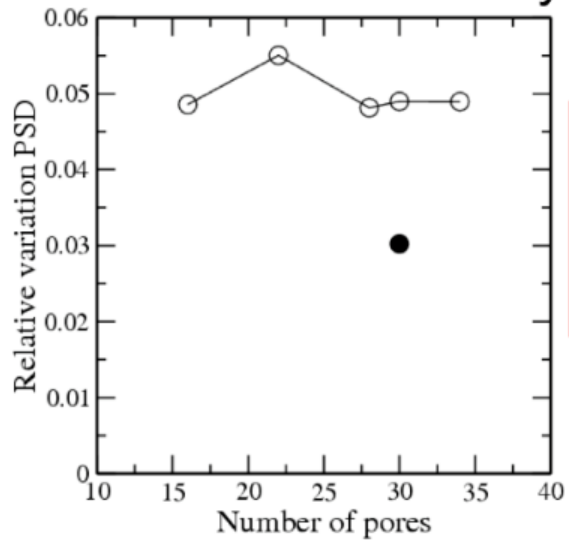

C1

C2

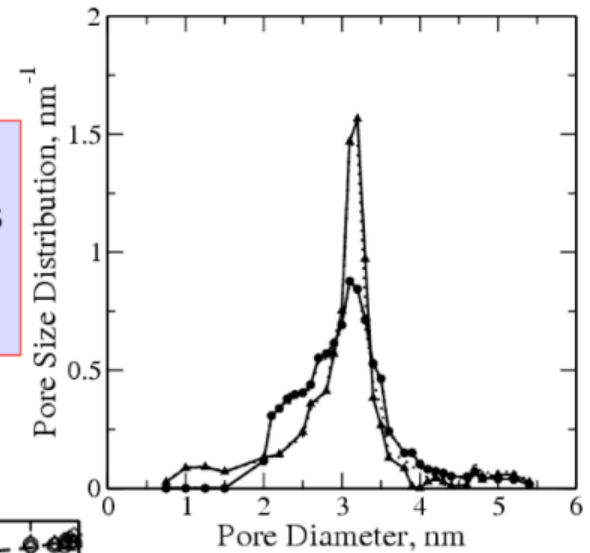

$$\min_x \{ \|a_e - A_s x\|_2^2 + \lambda^2 \|R x\|_2^2 \}$$

PSD analysis for Silica Based Materials (II)

Protocol PSD analysis over AM-5

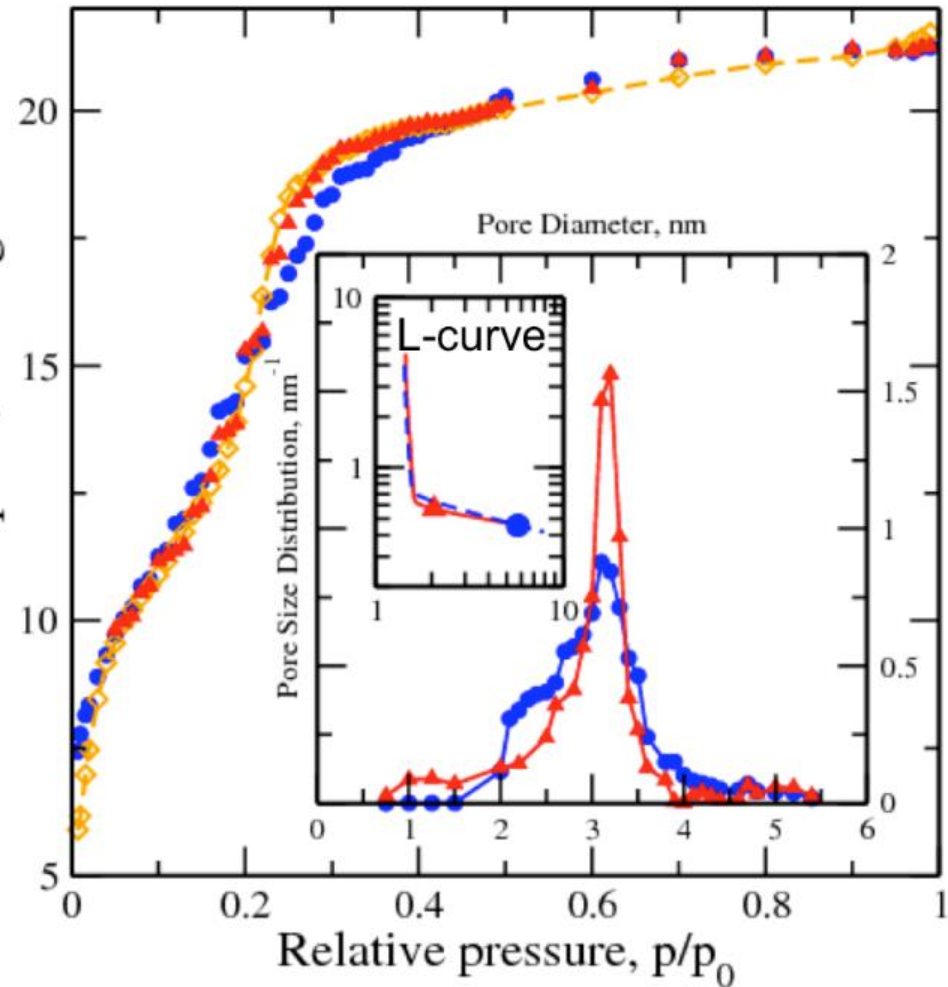

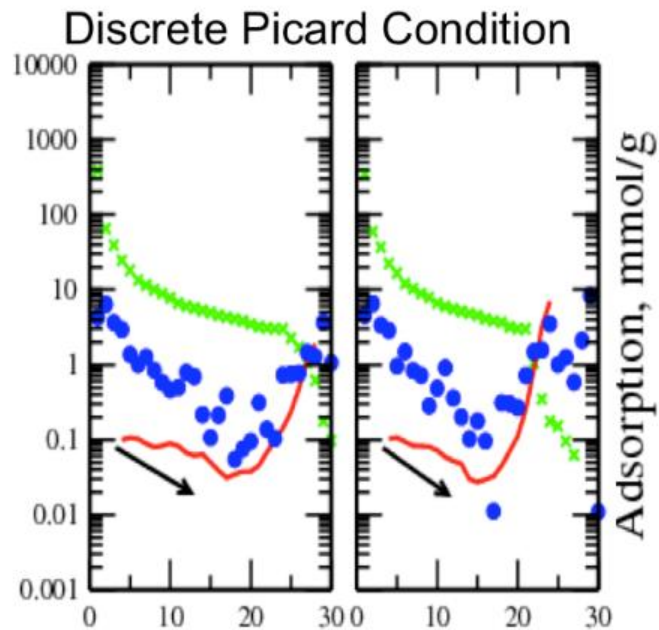

Robustness of the proposed PSD versus errors in the experimental data

PSD analysis for Silica Based Materials (I)

Protocol PSD analysis over AM-5
