3

Sar

The building principle of preferential attachment graphs is that

- An increasing family of graphs is constructed by adding vertices one-by-one.
- When a new vertex is introduced, it is linked by edges to a fixed or random number of existing vertices with a probability proportional to an increasing function *f* of their degree.

The building principle of preferential attachment graphs is that

- An increasing family of graphs is constructed by adding vertices one-by-one.
- When a new vertex is introduced, it is linked by edges to a fixed or random number of existing vertices with a probability proportional to an increasing function *f* of their degree.

The building principle of preferential attachment graphs is that

- An increasing family of graphs is constructed by adding vertices one-by-one.
- When a new vertex is introduced, it is linked by edges to a fixed or random number of existing vertices with a probability proportional to an increasing function *f* of their degree.
- In short: the higher the degree of a vertex, the more likely it is to attract further links.

The building principle of preferential attachment graphs is that

- An increasing family of graphs is constructed by adding vertices one-by-one.
- When a new vertex is introduced, it is linked by edges to a fixed or random number of existing vertices with a probability proportional to an increasing function *f* of their degree.
- In short: the higher the degree of a vertex, the more likely it is to attract further links.

We have analysed a mathematically convenient variant of such graphs. Crucially, the essential features of preferential attachment graphs should not depend on the choice of variant but only on the strength of the preferential attachment and the edge density.

Take parameters  $\mathbf{0} \leq \gamma < \mathbf{1}$  and  $\mathbf{0} < \beta < \mathbf{1}$  and choose the affine function

 $f: \mathbb{N} \cup \{0\} \to (0, \infty)$  given by  $f(k) = \gamma k + \beta$ .

## Preferential attachment graphs are scale-free

Our first result shows that the preferential attachment graphs with  $\gamma > 0$  are scale-free and identify the power law exponent.

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ - 日 ・

NQ C

### Preferential attachment graphs are scale-free

Our first result shows that the preferential attachment graphs with  $\gamma > 0$  are scale-free and identify the power law exponent.

Theorem 1 (M, Dereich 2008)

(a) Suppose  $X_n$  is the empirical indegree distribution of  $\mathcal{G}_n$ . Then

$$\lim_{n\uparrow\infty}X_n(k)=\mu(k)$$
 for all  $k$ , almost surely,

where

$$\mu(k) = \frac{1}{1+f(k)} \prod_{l=0}^{k-1} \frac{f(l)}{1+f(l)} \sim c \, k^{-(1+\frac{1}{\gamma})}.$$

(b) The conditional distribution of the outdegree of the (n + 1)st vertex, given the graph at time n, converges almost surely in the variational topology to the Poisson distribution with parameter ∑<sub>k=0</sub><sup>∞</sup> µ(k)f(k).

### Preferential attachment graphs are scale-free

Our first result shows that the preferential attachment graphs with  $\gamma > 0$  are scale-free and identify the power law exponent.

Theorem 1 (M, Dereich 2008)

(a) Suppose  $X_n$  is the empirical indegree distribution of  $\mathcal{G}_n$ . Then

$$\lim_{n\uparrow\infty}X_n(k)=\mu(k)$$
 for all  $k$ , almost surely,

where

$$\mu(k) = \frac{1}{1+f(k)} \prod_{l=0}^{k-1} \frac{f(l)}{1+f(l)} \sim c \, k^{-(1+\frac{1}{\gamma})}.$$

(b) The conditional distribution of the outdegree of the (n + 1)st vertex, given the graph at time n, converges almost surely in the variational topology to the Poisson distribution with parameter ∑<sub>k=0</sub><sup>∞</sup> µ(k)f(k).

 $\Rightarrow$  The empirical degree distribution converges to a power law with exponent

$$au := 1 + rac{1}{\gamma}.$$

### Comparison with other models

In the preferential attachment model we have, for  $m \leq n$ , that

$$\mathbb{E}[\text{indegree of } m \text{ at time } n] \approx \left(\frac{n}{m}\right)^{\gamma},$$

and hence

$$\mathbb{P}\{m \leftrightarrow n\} \approx \frac{1}{(m \wedge n)^{\gamma} (m \vee n)^{1-\gamma}}$$

◆□ > ◆□ > ◆ □ > ● □ >

### Comparison with other models

In the preferential attachment model we have, for  $m \leq n$ , that

$$\mathbb{E}\left[\mathsf{indegree} ext{ of } m ext{ at time } n
ight] pprox \left(rac{n}{m}
ight)^{\gamma},$$

and hence

$$\mathbb{P}\{m \leftrightarrow n\} \approx \frac{1}{(m \wedge n)^{\gamma} (m \vee n)^{1-\gamma}}.$$

If  $\gamma \neq \frac{1}{2}$  this is not the product of a function of *n* with a function of *m* and hence preferential attachment is not a rank one model.

## Comparison with other models

In the preferential attachment model we have, for  $m \leq n$ , that

$$\mathbb{E}\left[\mathsf{indegree} ext{ of } m ext{ at time } n
ight] pprox \left(rac{n}{m}
ight)^{\gamma},$$

and hence

$$\mathbb{P}\{m \leftrightarrow n\} \approx \frac{1}{(m \wedge n)^{\gamma}(m \vee n)^{1-\gamma}}.$$

If  $\gamma \neq \frac{1}{2}$  this is not the product of a function of *n* with a function of *m* and hence preferential attachment is not a rank one model.

This makes our model much more difficult to study than rank one models such as

- the LCD-model of Bollobas and Riordan, which is a preferential attachment model that necessarily has  $\gamma = \frac{1}{2}$ , or, equivalently,  $\tau = 3$ .
- the configuration model which, loosely speaking, is the uniform distribution on the collection of graphs with a given power law degree distribution.

#### Questions:

- (1) For which parameters  $\beta$ ,  $\gamma$  is there a giant component?
- (2) When is the network robust?
- (3) What is the size of the giant component near criticality?

《日》 《圖》 《臣》 《臣》

= 990

#### Questions:

- (1) For which parameters  $\beta, \gamma$  is there a giant component?
- (2) When is the network robust?
- (3) What is the size of the giant component near criticality?

#### Earlier work:

- In the case that  $\gamma = 0$  so that there is no preferential attachment the model was first studied by Dubins (1984). The questions were answered by Shepp (1989) and Riordan (2005).
- For the LCD model the questions were answered by Bollobas, Riordan (2003) and Riordan (2005).

## Coupling the graph to a branching process

The answers to our questions are based on a coupling of the neighbourhood of a randomly chosen vertex to the genealogy of a killed branching random walk.

NQ CV

The answers to our questions are based on a coupling of the neighbourhood of a randomly chosen vertex to the genealogy of a killed branching random walk.

Particle positions are on the real line and types are given by the relative position of their father. Define the pure birth process  $(Z_t: t \ge 0)$  by its generator

$$Lg(k) = f(k) \left(g(k+1) - g(k)\right).$$

The answers to our questions are based on a coupling of the neighbourhood of a randomly chosen vertex to the genealogy of a killed branching random walk.

Particle positions are on the real line and types are given by the relative position of their father. Define the pure birth process  $(Z_t: t \ge 0)$  by its generator

$$Lg(k) = f(k) \left(g(k+1) - g(k)\right).$$

A particle which has its parent to its left generates offspring

- to its right with relative positions at the jumps of the process  $(Z_t: t \ge 0)$ ;
- to its left with relative positions distributed according to the Poisson process Π on (-∞, 0] with intensity measure e<sup>t</sup> E[f(Z<sub>-t</sub>)] dt.

For  $\tau > 0$  we let  $(Z_t^{(\tau)}: t \ge 0)$  be the pure birth process  $(Z_t: t \ge 0)$  conditioned to have a birth at time  $\tau$  with that particle removed.

Miracle: The law of  $(Z_t^{(\tau)}: t \ge 0)$  does not depend on  $\tau$ !

For  $\tau > 0$  we let  $(Z_t^{(\tau)}: t \ge 0)$  be the pure birth process  $(Z_t: t \ge 0)$  conditioned to have a birth at time  $\tau$  with that particle removed.

Miracle: The law of  $(Z_t^{(\tau)}: t \ge 0)$  does not depend on  $\tau$ !

A particle which has its parent to its right generates offspring

- to its right with relative positions at the jumps of  $(Z_t^{(\tau)}(t): t \ge 0)$ .
- to its left in the same manner as before.

We start the branching random walk with one initial particle in location -X, where X is standard exponential and kill particles and their offspring if their position is to the right of the origin.

### Size of the giant component near criticality

Denote by  $\zeta(\gamma,\beta)$  the size of the giant component which is the asymptotic proportion of vertices in the largest graph component.

# Theorem 3 Eckhoff, M (2013) (a) Let $0 \le \gamma < \frac{1}{2}$ and denote $\beta_c(\gamma) = \frac{(\frac{1}{2} - \gamma)^2}{1 - \gamma}$ . Then $\lim_{\beta \downarrow \beta_c(\gamma)} \sup \sqrt{\beta - \beta_c(\gamma)} \log \zeta(\gamma, \beta) \le -\frac{\pi}{2} \frac{1}{\sqrt{1 - \gamma}}.$ (b) Let $0 < \beta < \frac{1}{4}$ and denote $\gamma_c(\beta) = \frac{1}{2}(1 - \beta - \sqrt{\beta^2 + 2\beta})$ . Then $\lim_{\gamma \downarrow \gamma_c(\beta)} \sqrt{\gamma - \gamma_c(\beta)} \log \zeta(\gamma, \beta) \le -\frac{\pi}{2} \left(\frac{1}{\beta^2 + 2\beta}\right)^{\frac{1}{4}}.$

### Size of the giant component near criticality

Denote by  $\zeta(\gamma,\beta)$  the size of the giant component which is the asymptotic proportion of vertices in the largest graph component.

Remark: This is in stark contrast to the behaviour of the configuration model!

## Size of the giant component: Idea of proof

We need to give an upper bound on the survival probability of the killed branching process. Our arguments adapt a technique from a recent paper by Gantert, Hu and Shi (2011) to our setup.

Sac

# Size of the giant component: Idea of proof

We need to give an upper bound on the survival probability of the killed branching process. Our arguments adapt a technique from a recent paper by Gantert, Hu and Shi (2011) to our setup.

Main ingredients of the proof

- the basis is a truncated first moment method,
- use a many-to-one lemma,
- adapt and use a large deviation theorem for Markov chains.

Theorem 6 Eckhoff, M (2012) Suppose  $X_n^{(\varepsilon)}$  is the empirical indegree distribution of  $\mathcal{G}_n^{(\varepsilon)}$ . Then  $\lim_{n\uparrow\infty} X_n(k) = \mu^{(\varepsilon)}(k)$  for all k, almost surely, where the limiting measure  $\mu^{(\varepsilon)}$  is deterministic and satisfies  $\lim_{k\to\infty} \frac{1}{k} \log \mu^{(\varepsilon)}(k,\infty) = \log(1-\varepsilon^{\gamma}).$ 

Remark: After the attack the network is no longer scale-free. Instead its asymptotic degree distribution has exponential tails.

Preferential attachment graphs with  $\gamma > \frac{1}{2}$  are ultrasmall. More precisely, for vertices  $V_n, W_n$  chosen uniformly from the giant component of  $\mathcal{G}_n$  we have

$$d_{\mathcal{G}_n}(V_n, W_n) \sim rac{4 \log \log n}{\log rac{\gamma}{1-\gamma}}$$
 in probability,

see Dereich, Mönch, M (2011) and Dommers, van der Hofstad, Hooghiemstra (2010).

Preferential attachment graphs with  $\gamma > \frac{1}{2}$  are ultrasmall. More precisely, for vertices  $V_n$ ,  $W_n$  chosen uniformly from the giant component of  $\mathcal{G}_n$  we have

$$d_{{\mathcal{G}}_n}(V_n,W_n)\sim rac{4\log\log n}{\lograc{\gamma}{1-\gamma}}$$
 in probability,

see Dereich, Mönch, M (2011) and Dommers, van der Hofstad, Hooghiemstra (2010).

## Theorem 7 Eckhoff, M (2012)

Suppose that  $\varepsilon > 0$  is sufficiently small so that  $\mathcal{G}_n^{(\varepsilon)}$  has a giant component. and let  $V_n, W_n$  be independent, uniformly chosen vertices in  $\mathcal{G}_n$ . Then, for all  $\delta > 0$ ,

$$d_{\mathcal{G}_n^{(\varepsilon)}}(V_n, W_n) \geq \frac{1-\delta}{\log(1/\rho_c(\varepsilon))} \log n \qquad \text{with high probability}.$$

## Theorem 7 Eckhoff, M (2012)

Suppose that  $\varepsilon > 0$  is sufficiently small so that  $\mathcal{G}_n^{(\varepsilon)}$  has a giant component. and let  $V_n, W_n$  be independent, uniformly chosen vertices in  $\mathcal{G}_n$ . Then, for all  $\delta > 0$ ,

$$d_{\mathcal{G}_n^{(arepsilon)}}(V_n,W_n) \geq rac{1-\delta}{\log(1/
ho_c(arepsilon))}\log n \qquad$$
 with high probability.

Remarks: After the attack the network is no longer ultrasmall, and typical distances are now logarithmic, i.e. much larger. The lower bound is conjectured to be sharp.

In particular preferential attachment graphs are scale free, and if the power-law exponent is in the range 2  $<\tau<$  3, they are

- ultrasmall,
- robust to blind attack, but
- vulnerable to targeted attack.

Sar

In particular preferential attachment graphs are scale free, and if the power-law exponent is in the range 2  $<\tau<$  3, they are

- ultrasmall,
- robust to blind attack, but
- vulnerable to targeted attack.
- A targeted attack drastically changes the topology of the graph, and the network is no longer scale-free, ultrasmall or robust.

In particular preferential attachment graphs are scale free, and if the power-law exponent is in the range 2  $<\tau<$  3, they are

- ultrasmall,
- robust to blind attack, but
- vulnerable to targeted attack.
- A targeted attack drastically changes the topology of the graph, and the network is no longer scale-free, ultrasmall or robust.
- Preferential attachment graphs are mathematically tractable. The main tool for such an analysis is an approximation of local neighbourhoods by branching random walks and advanced methods from the theory of branching processes.
